### What is DHCP?

The Dynamic Host Configuration Protocol (DHCP) is a network management protocol used on Internet Protocol (IP) networks, whereby a DHCP server dynamically assigns an IP address and other network configuration parameters to each device on the network, so they can communicate with other IP networks. A DHCP server enables computers to request IP addresses and networking parameters automatically from the Internet service provider (ISP), reducing the need for a network administrator or a user to manually assign IP addresses to all network devices. In the absence of a DHCP server, a computer or other device on the network needs to be manually assigned an IP address, or to assign itself an APIPA address, the latter of which will not enable it to communicate outside its local subnet.

### DHCP Server Installation:

Standard DHCP server implementation available in various Linux distributions is an Open source version maintained by ISC ( Internet System Consortium ).

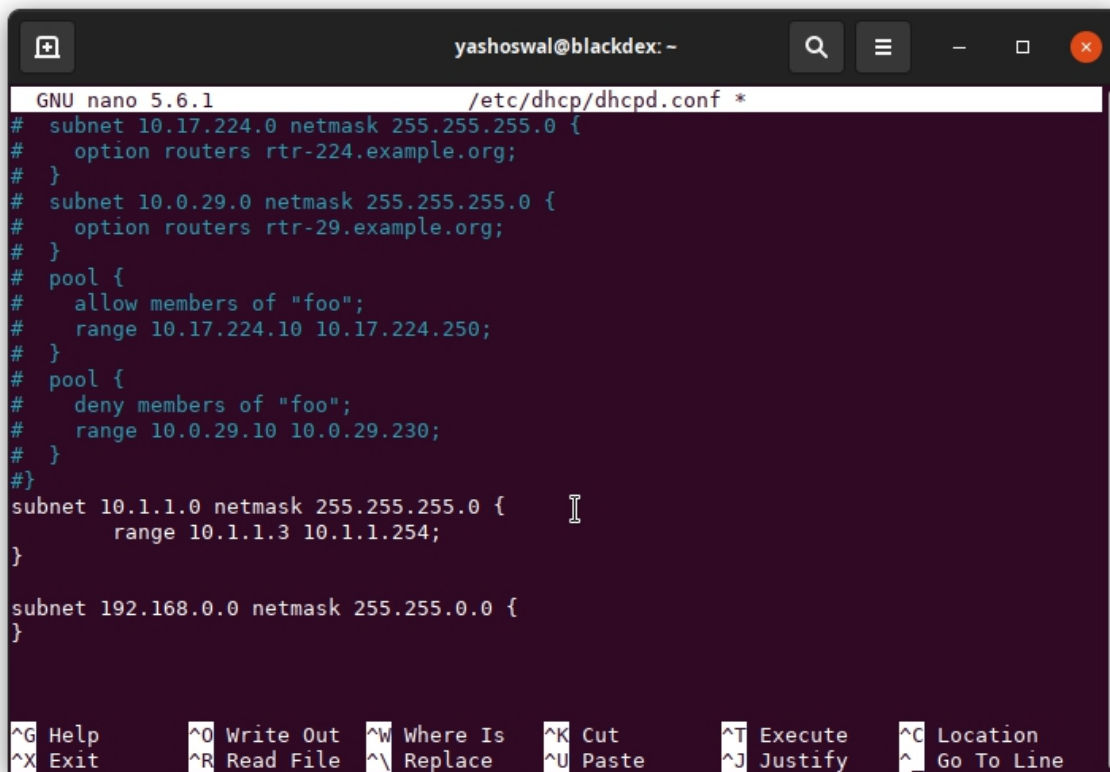

● `sudo apt-get install isc-dhcp-server`

```
yashoswal@blackdex: ~$ sudo apt-get install isc-dhcp-server
Reading package lists... Done
Building dependency tree... Done
Reading state information... Done
isc-dhcp-server is already the newest version (4.4.1-2.3ubuntu1).
0 upgraded, 0 newly installed, 0 to remove and 0 not upgraded.
yashoswal@blackdex: ~$
```

## Basic DHCP Configuration

By default, DHCP server configuration does not include any subnets on which DHCP server should lease IP addresses. Therefore, depending on your Linux system you may get the following error message when you attempt to start DHCP with the default `dhcpd.conf` configuration file.

```
GNU nano 5.6.1 /etc/dhcp/dhcpd.conf *
# subnet 10.17.224.0 netmask 255.255.255.0 {
#   option routers rtr-224.example.org;
# }
# subnet 10.0.29.0 netmask 255.255.255.0 {
#   option routers rtr-29.example.org;
# }
# pool {
#   allow members of "foo";
#   range 10.17.224.10 10.17.224.250;
# }
# pool {
#   deny members of "foo";
#   range 10.0.29.10 10.0.29.230;
# }
#}
subnet 10.1.1.0 netmask 255.255.255.0 {
    range 10.1.1.3 10.1.1.254;
}

subnet 192.168.0.0 netmask 255.255.0.0 {
}
```

Then restart your dhcp service by

- `sudo systemctl restart isc-dhcp-server`

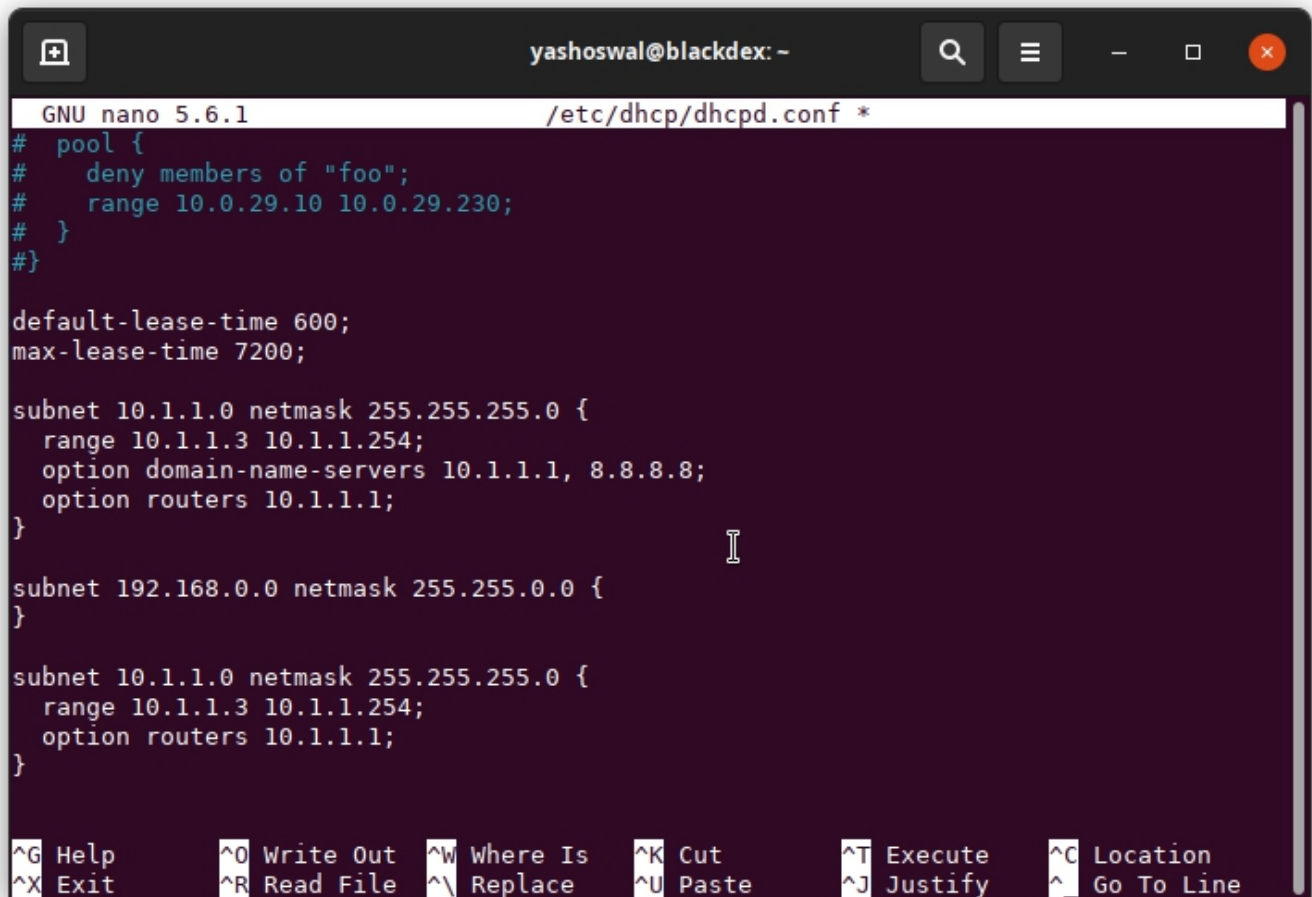

This configuration file instructs DHCP server to listen for DHCP client requests on subnet 10.1.1.0 with netmask 255.255.255.0. Furthermore, it will assign IP addresses in range 10.1.1.3 - 10.1.1.254. It also defines an empty definition for subnet with network ID 192.168.0.0

## Define DNS Server

Another configuration parameter possible to be set by DHCP server to its client is a definition of DNS server. If you want your clients to use DNS server with an IP address 8.8.8.8 (Google DNS server) and 10.1.1.1 you can do it by including an option domain-name-servers to DHCP's configuration file.

## Set default gateway

DHCP also allows for a client's gateway configuration. To set any client on the local network to use default gateway 10.1.1.1, add line option routers 10.1.1.1 into `dhcpd.conf`

A terminal window titled 'yashoswal@blackdex: ~' showing the nano 5.6.1 editor editing the file '/etc/dhcp/dhcpd.conf'. The configuration includes a 'pool' section with a deny rule for 'foo' and a range of 10.0.29.10 to 10.0.29.230. It also sets default and maximum lease times to 600 and 7200 seconds respectively. Three subnet declarations are present: the first for 10.1.1.0/24 with domain servers 10.1.1.1 and 8.8.8.8, and routers at 10.1.1.1; the second for 192.168.0.0/24; and the third for 10.1.1.0/24 with a range of 10.1.1.3 to 10.1.1.254 and a router at 10.1.1.1. The bottom status bar shows various nano editor shortcuts.

```
GNU nano 5.6.1 /etc/dhcp/dhcpd.conf *
# pool {
#     deny members of "foo";
#     range 10.0.29.10 10.0.29.230;
# }
#}

default-lease-time 600;
max-lease-time 7200;

subnet 10.1.1.0 netmask 255.255.255.0 {
    range 10.1.1.3 10.1.1.254;
    option domain-name-servers 10.1.1.1, 8.8.8.8;
    option routers 10.1.1.1;
}

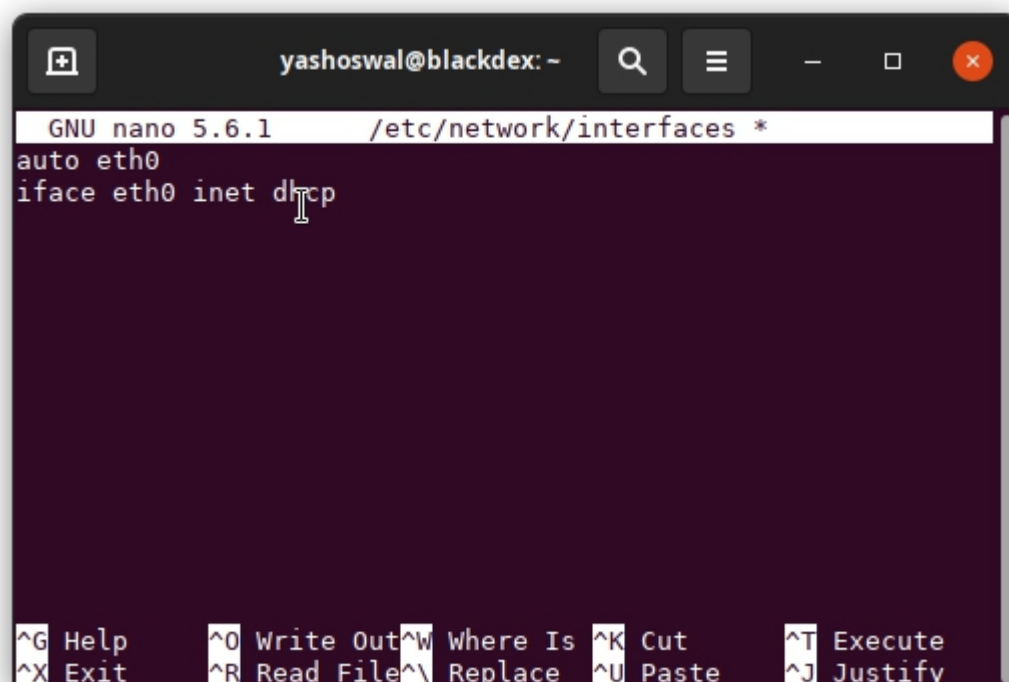

subnet 192.168.0.0 netmask 255.255.0.0 {
}

subnet 10.1.1.0 netmask 255.255.255.0 {
    range 10.1.1.3 10.1.1.254;
    option routers 10.1.1.1;
}

^G Help      ^O Write Out ^W Where Is  ^K Cut       ^T Execute  ^C Location
^X Exit      ^R Read File ^\ Replace   ^U Paste     ^J Justify  ^_ Go To Line
```

## Other Configuration Options

To configure your client to use a DHCP on a network interface eth0 on Ubuntu or Debian Linux systems enter the following lines in your **/etc/network/interfaces** file:

A terminal window titled 'yashoswal@blackdex: ~' showing the nano 5.6.1 editor editing the file '/etc/network/interfaces'. The configuration consists of two lines: 'auto eth0' and 'iface eth0 inet dhcp'. The bottom status bar shows various nano editor shortcuts.

```
GNU nano 5.6.1 /etc/network/interfaces *
auto eth0
iface eth0 inet dhcp

^G Help      ^O Write Out ^W Where Is  ^K Cut       ^T Execute  ^C Location
^X Exit      ^R Read File ^\ Replace   ^U Paste     ^J Justify  ^_ Go To Line
```
